location setup

a. introduction

Baseball™ is a new one- or two-player video game designed by Atari. The game rules, catching, pitching and batting are realistically displayed on the screen, accompanied by sounds of crowd cheers, noise, the crack of the bat, and a ball sound.

Player controls are mounted at either end of the game. The player controls consist of two multi-function LED pushbutton switches and Trak Ball™ controls. (The switches' functions are described in the graphics on the control panel.) The Trak Ball rolls smoothly with a shove from the palm of your hand: this moves either the batter or out-fielders on the screen.

Baseball™

b. game inspection

Your new Baseball game is manufactured ready to play immediately after removal from the shipping carton. Your cooperation is desired in order to supply the final touch of quality control to your game. Therefore, please follow the procedures below to ensure that your game is in good condition:

1. Examine all external parts of the game cabinet for dents, chips, or broken parts.
2. After determining that the game has been received in good condition, unlock and open the access panel. Carefully inspect the interior and verify the following:
 - All plug-in connectors are firmly seated.
 - All integrated circuit packages (chips, ICs) in sockets on the game printed circuit board are firmly seated.
 - No harness wires are disconnected.
 - No loose foreign objects are present, especially metal objects that could cause electrical problems.

Be sure that all major assemblies are checked. Check the game printed circuit board (PCB), the speakers, player controls and the TV monitor for secure mounting.

Note the location of the game's serial number—it is on a metallic label attached to the left side of the game cabinet (as you face the coin door). A serial number (not necessarily the same one) also appears in the corner of the PCB that's common to both edge connectors, inside the game cabinet. See the illustration on the inside front cover of this manual.

Please mention this number(s) whenever calling your distributor for service.

c. voltage selection

Use one of the following four plugs to set the proper voltage for your game. If you have any problems with your game as described in either paragraph below, then change the voltage plug as required.

| Line Voltage Range | Voltage Selection Plug Color |
|--------------------|----------------------------------|
| 86-104 VAC | Black |
| 100-125 VAC | Orange (installed at factory) |
| 190-220 VAC | Green |
| 210-240 VAC | Red |

1. Low-Voltage Problems

If your game is set for 110 VAC (or 220 VAC) and your line voltage is usually below 110 VAC (or 200 VAC), you may experience a decrease in the size of the monitor picture and/or the game operation will be erratic (weird things will appear on the screen).

2. High-Voltage Problems

If your game is set for 95 VAC (or 210 VAC) and your line voltage is usually above 110 VAC (or 220 VAC), the monitor picture size may increase, the game will run hotter, and the game will be prone to an increased rate of failures.

Figure 1-1 Voltage Selection Plugs

d. interlock and power on/off switches

To minimize the hazard of electrical shock while you are working on the inside of the game cabinet, two interlock switches have been installed (see Figure 1-2). One is located behind the access panel and one behind the coin door. Any of these switches will disconnect all the AC line voltage from the game circuitry.

Check for proper operation of the interlock switches by performing the following steps:

1. Unlock and open the access panel and the coin door.
2. Plug the AC line power cord into your local AC outlet.
3. Set the power on/off switch to the on position.

4. Close the access panel and coin door. Within approximately 30 seconds after closing the last door, the TV monitor should display a picture. (The game lighting should light immediately.)
5. Slowly open either door. The TV picture should disappear and the game lighting go off when either the access panel or coin door is opened approximately 2½ cm (one inch).
6. If the results of step 5 are satisfactory, the interlock switches are operating properly. If the picture and lights stay on, check to see if either interlock switch is broken from its mounting or stuck in the on position.
7. Close and lock the access panel.

NOTE:
WHEN TROUBLESHOOTING WITH THE
DOOR(S) OPEN, YOU MAY DEFEAT THE
INTERLOCK SWITCHES BY PULLING INTER-
LOCK PLUNGER OUT AS INDICATED BY
DIRECTION OF ARROW.

Figure 1-2 Location of Interlock and Power On/Off Switches

e. self-test procedure

This game will test itself and provide data on the TV monitor and speakers to demonstrate that its circuitry and controls are working properly. No additional equipment is required. See Figure 1-3 for location of the self-test switch. To start the procedure, slide this switch to *on* as indicated in the figure.

See Table 1-1 for further details and instructions on the self-test. We suggest that you perform the self-test each time the coin box is emptied.

f. volume adjustment

If the volume is incorrect for your location, open the coin door and adjust the volume control as indicated in Figure 1-3.

Figure 1-3 Location of Self-Test Switch and Volume Control

Table 1-1 Self-Test Procedure

Open the coin door. Locate the self-test switch inside the cabinet on a metal bracket. It's to the right and slightly below the door opening. Slide the switch to *on*.

| Instruction | Result if Test Passes | Result if Test Fails |
|---|---|---|
| Preliminary Test | Crowd noise is turned on. | No crowd noise: Indicates a defective speaker, volume control set too low, or faulty crowd noise circuitry. |
| 1. RAM/ROM Test | TV monitor displays RAM OK ROM OK | Monitor displays the message BAD RAM if the random-access memory is at fault. Monitor displays the message BAD ROM if a read-only memory is at fault. |
| 2. Trak Ball™ Test Roll the Trak Ball in all directions. | Two white figures will appear on the monitor, one for each Trak Ball control. They will move exactly as the control is moved—up/down, right/left, and diagonally at both angles. | One or both white figures are not displayed, or one or more directions of movement will not respond, such as up/down. Suspect a bad steering PCB on the Trak Ball or bad steering circuitry on the game PCB. |
| 3. Switch/Crowd Cheer Audio Test Move the Trak Ball and then press each of these switches: • play/select switches • coin door switches • slam switch | For each pressed switch another white figure will be frozen onto the screen wherever the rolling Trak Ball last placed the moving white figure. Switch pressure will also cause a crowd cheer to be heard simultaneously from both speakers. | No crowd cheer and no white figure frozen on screen indicates bad switch. White figure frozen on screen but no crowd cheer indicates bad crowd cheer audio circuitry. |

Return the Self-Test Switch to its *off* position; then close the coin door.

g. operator options

The operator options offer maximum player appeal for your game's location. These options are listed in Table 1-2. They are preset for a certain game set-up during production.

To change the toggle positions of the switch assembly and set the desired options, you do not have to remove the

game PCB. Unplug the game, and open the access panel. Then locate the four-toggle switch assembly on the PCB near the edge connector (see Figure 1-4).

Set the toggles for the desired options as listed in Table 1-2. Close and lock the access panel. Plug the game in and verify attract mode.

Table 1-2 Option Switch Settings

| Switch Settings on 4-Toggle DIP Switch (located at position K10 on the game PCB) | | | | Result |
|---|-----|---|----------|--|
| 1 | 2 | 3 | 4 | |
| Off | Off | | | Most difficult setting: Infielders are excellent players and innings are shortest. |
| On | Off | | | |
| Off | On | | Not Used | } Intermediate settings |
| On | On | | | Easiest setting: Infielders are poor players and innings are longest. |

Atari recommends, at least for initial location setup, using one of the two middle settings. Regardless of the setting, the infielders always get better as the inning progresses to provide challenge for the players.

Figure 1-4 Option-Setting Switches

game play

The Baseball™ game has four basic modes of operation: attract, ready-to-play, play and the self-test. The *attract mode* starts after the play mode or after power-up. It ends when a coin has been inserted into either coin slot. The *ready-to-play mode* begins after a coin has been inserted. It ends with the pressing of either LED switch.

The *play mode* starts whenever a player presses an LED switch. The game does not automatically start after a certain time has elapsed. The *self-test* is a special mode used for verifying proper game operation. It begins with the self-test switch set to on, and ends when the switch is set to off.

2

Baseball™

a. attract mode

The attract mode is specifically programmed to attract potential players by displaying the basic sequence of game play. The fielders run out to their respective places on the playfield, pitches are made, batters run around all the bases, and three outs finally cause the diamond to invert by 180°. The game repeats this sequence, so that the opposing side of the cabinet is now "playing".

Scores for balls, strikes, and outs are totalled and displayed as the attract-mode sequence progresses. In addition, the *INSERT COINS* and appropriate coinage phrases are displayed at the ends of the screen. No sound is generated during this mode.

b. ready-to-play mode

This mode starts when either coin switch is activated by a coin. Crowd noise begins at this point. Both sides of the TV monitor flash the message *PUSH START* until a player pushes either LED switch.

c. play mode

Fielders run from the dugout to their proper places. The game will prompt the players to select one of the four types of hits or pitches by flashing *SELECT PITCH* or *SELECT HIT* on the ends of the screen. A player chooses a hit or pitch by pressing his or her play select switch until the indicator LED corresponding to the hit or pitch selected is lit. If the player does not do so, the game will automatically choose the hit or pitch randomly.

As a player successfully hits the ball, control of the runner is gained by rolling the Trak Ball™ in the proper diagonal direction toward first base, and so on around the diamond. The crowd noise increases with a triple, home run, score or out.

Scoring is exactly as in actual games, i.e., three strikes equals an out, four balls equals a walk, and three outs mean that side retires. Coinage of the Baseball game for the first inning is one coin per player. The second and subsequent innings each cost one coin, regardless of the number of players.

maintenance and adjustments

Due to its solid-state circuitry, this Atari unit should require very little maintenance and only occasional adjustment. Information given in this chapter and elsewhere in this manual is intended to cover most servicing situations that may be encountered at the game site. The procedures given are in sufficient detail to be understood by a person with moderate technical background.

a. cleaning

The exterior of the game cabinet and the glass and acrylic panels may be cleaned with any non-abrasive household cleaner. If desired, special coin machine cleaners that leave no residue can be obtained from your distributor. Do not dry-wipe the small acrylic play select panel, because any dust can scratch the surface and result in fogging the plastic. (The large monitor shield is made of tempered glass and should be scratch-resistant.)

b. fuse replacement

Baseball contains six fuses, five on the power supply assembly, and one on the floor of the cabinet (not including TV monitor). Replace fuses only with the same type as shown in Figure 3-1. See the manual on the TV monitor for additional monitor fuse data.

Figure 3-1 Fuse Replacement

c. control panel access

Prior to replacing any removable component from the control panel or prior to removing the TV monitor, unplug the game and follow the steps outlined in Figure 3-2.

1. Unfasten and remove three allen-head screws from control panel.
2. Carefully swing the control panel open.

Figure 3-2 Control Panel Access

1. LED Switch Replacement

The light-emitting diode (LED) switch on top of the control panel has a very low failure rate. In case the switch should ever be suspect, first test it. To test or replace the switch, refer to Figure 3-3.

2. Play Select PCB Repairs

Two problems could occur with this PCB. A light-emitting diode could burn out, or one of the six incandescent lamps could burn out. To replace any LED or lamp, open the control panel and remove this small PCB as described in Figure 3-4.

- Remove all wires from the faulty switch.
- Turn the switch counterclockwise while holding the cone-shaped nut on the outside of the control panel.
- Install a new switch using the reverse procedure.
- Reconnect the harness wires.

DOUBLE-POLE SINGLE-THROW (DPST) SWITCH WITH INTERNAL LED

Figure 3-3 L.E.D. Switch Replacement

1. Open control panel as illustrated in Figure 3-2.
2. Remove the two washers and nuts.
3. Unplug the white connector.
4. Remove the play select PCB.
5. Replace lamp or light-emitting diode, as needed. The lamps are NEMA type no. 47 (Atari part no. 70-11-47).

Figure 3-4 Play Select PCB Removal

3. Trak Ball™ Maintenance and Repair

To maintain this control, you will only have to lubricate the bearings approximately every 4,000 innings or \$1,000 in income earned. The number of innings can be read off the coin counter, located on the coin door. Use *only two drops* of 3-in-One® oil in each of the ball bearings. (Each Trak Ball control has five bearings.)

For further instructions on how to replace the trak ball or either steering PCB, see Figure 3-5.

4. TV Monitor Removal

If you should need to service or replace the 23-inch TV monitor, you must first remove it from the game cabinet. Follow the instructions in Figure 3-6.

3-4 Baseball™

d. game pcb removal

You may wish to remove the game PCB for service or inspection. To do this, proceed as follows:

- Open the access panel.
- Locate the two screws that secure the game PCB in its slots, and remove them.
- Unplug the edge connector; then carefully slide the PCB straight out of its slots. Be careful not to twist the board, as this may loosen connections or components.
- Replace or repair as required.
- Reinstall the PCB, making sure that the edge connector is properly plugged in. Note it is keyed to fit on only one way, so if it doesn't slip on easily, don't force it! A reversed edge connector may damage the game!
- Replace the securing screws through the holes in the PCB.
- Close and lock the access panel.
- Check that the operation of the game is correct by performing the self-test.

Figure 3-5 Trak Ball™ Control Repair

CAUTION

High voltages exist in any television unit, even with power disconnected. Use extreme caution and do not touch electrical parts or the TV chassis with your hands or with metal objects in your hands!

1. Open control panel above and to the right of the coin door as shown in Figure 3-2. Open the coin door.
2. Carefully loosen tape at exposed end of cardboard bezel. Do not remove the bezel.
3. Open access panel.
4. Unplug control panel connector for opened player control panel.
5. Remove the four TV monitor carriage bolts and associated hardware.
6. Unplug TV monitor chassis connector.
7. Slide out TV monitor shelf assembly along with the bezel; the opened control panel is attached to the assembly.

Figure 3-6 TV Monitor Removal

details of electronic operation

This chapter provides a general overview of the operation of the circuitry contained on the game printed circuit board (PCB). This information has been organized with an emphasis placed on troubleshooting the game PCB circuit by circuit.

The Baseball game block diagram of Figure 4-1 illustrates the major components, including all controls remote to the game PCB. The function and direction of the information to and from these various controls is also shown.

The game PCB block diagram in Figure 4-2 illustrates the division and function of the various circuits located on the game PCB and how they are controlled by the microprocessor. Refer to Figure 4-2 as you go through the following circuit descriptions.

Baseball™

Figure 4-1 Game Block Diagram

Figure 4-2 Game PCB Block Diagram

a. power supply

(See Figure 4-3)

The power supply (located on the bottom) produces all the necessary game power as shown in Figure 4-3.

The game PCB receives an unregulated +10 volts DC at pins B and 2 of the PCB edge connector. The +10 volts DC is rectified in the power supply assembly and regulated to a stable +5 volts DC by the LM323 on the game PCB. The regulated +5 volts DC is distributed throughout the

PCB to power all logic circuits (see Figure 4-4).

The 25 volts AC is received by the game PCB on pins W, X, and 20 and rectified by diodes CR1 and CR2, then filtered by capacitor C62. Zener diode CR3 regulates the +18 volts DC to +12 volts DC. This voltage powers the LM324 IC in the audio circuitry.

The unregulated +18 volts DC is used to supply the TDA2002 audio amplifier in the audio circuitry.

Power Supply

Coin Door

Figure 4-3 Game Power Distribution and Wiring Diagram

Figure 4-3 (Continued) Game Power Distribution and Wiring Diagram

(034562-01 B)

b. sync generator

(See Figure 4-5)

The basic frequency of the sync generator is a 12.096-MHz clock, generated by a crystal-controlled oscillator consisting of crystal Y1, inverter N4 and several discrete components. The output of the oscillator is 12 MHz. Examination of this signal with an oscilloscope (at pin 2 of N4) should show a period (or one cycle) of approximately 83 nanoseconds (.083 microseconds).

This base frequency is then divided down by binary counters P5, P6 and N6. These provide the various horizontal synchronization frequencies (1H thru 256H). The final output of this horizontal counter chain is 256H (at pin 13 of N6). This signal is, in effect, a division of the base frequency by 768, or 15,750 Hz. The period of 256H is about 63.5 microseconds. The 256H signal, as well as other horizontal signals, are used to generate the HBLANK and HSYNC timing pulses at flip-flop N5. See Figure 4-9 for the relative timing of these waveforms.

The HSYNC signal is used to clock two stages of vertical sync counters M5 and M6. The HSYNC signal is divided down by these counters to form the various vertical synchronization frequencies (1V thru 128V). These two stages are used, in effect, to do a divide by 262 of the HSYNC signal. This results in the final output of these counters (128V at pin 11 of M6) to be at a frequency of 60Hz (the period is approximately 16.6 milliseconds). The various vertical frequencies address a sync PROM (L5) whose data is latched at the output of L6. The outputs of this latch are the various polarities and phases of the vertical timing frequencies used to synchronize the TV monitor display. See Figure 4-9 for the relative timing of these waveforms.

The end result of the horizontal and vertical timing waveforms is to synchronize the TV monitor display. This display consists of 262 horizontal lines per frame, with each line being the equivalent of 768 (12 MHz) clock pulses. Each frame is repeated 60 times per second, providing the necessary frequency of display refresh to provide a stable, non-flickering display.

**Figure 4-4 Game PCB Power Distribution
(Part of 034634-XX B)**

**Figure 4-5 Sync Circuitry
(Part of 034634-XX B)**

C. microcomputer circuitry

The heart of the game PCB is the microcomputer circuitry. A brief description of the major components and their functions is provided in the following paragraphs. Note that the microcomputer components include the following:

1. MPU at location C2, address buffers at B1 and C1, and data buffers at location E2 (see Figure 4-6).
2. ROM memory at locations M1, N0, N1 and P1 for the -02 version, or PROM memory at B0, C0, D0, D1, E0, E1, F0, F1, H0, H1, J0, J1, K0, K1 and M0 for the -01 version (see Figure 4-7).
3. RAM memory at locations N2 and M2 (see Figure 4-8).
4. Address decoding circuitry B3, C7 and associated gates (see Figure 4-9).

**Figure 4-6 Microprocessor Circuitry
(Part of 034634-XX B)**

-01 PROM VERSION

-02 ROM VERSION

Figure 4-7 Program Memory
(Part of 034634-XX B)

5. Watchdog reset counter A4 and associated circuitry (see Figure 4-6).

MPU, ROM, and RAM

(See Figure 4-6, 4-7 and 4-8)

The microprocessor (MPU) is the "master controller" of all action that takes place in the game circuitry. Upon initialization, the MPU (via ABUS0 thru ABUS15) addresses data locations in the program ROMs or PROMs. The data in the addressed locations is then read by the MPU via the 8-bit data bus (D0 thru D7). The MPU decodes this data to determine what action it is to perform next (i.e., "read coin switch 1", "HIT", etc.). The MPU uses RAM memory to temporarily store information which it will later recall. The MPU is capable of writing (or putting data into) the RAM and then later reading (pulling data out of the RAM, via address bus ABUS0 thru ABUS15 and bi-directional data bus D0 thru D7).

Address Decoding Circuitry

(See Figure 4-9)

The MPU address decoding circuitry performs the critical function of turning on or enabling the appropriate game circuitry (i.e., RAM, ROM, latches, etc.) at the correct time, so that information can be transferred back and forth between the game circuitry and the MPU. Table 4-1 is the memory map for this game.

$\Phi 0$ Clock Driver

(See Figure 4-6)

The basic operating frequency of the MPU is established by its $\Phi 0$ input (on pin 37 of the MPU). The MPU runs at an operating frequency of 750 KHz. Examination of the MPU $\Phi 2$ output waveform (pin 39) with an oscilloscope should show a signal with a period of 1.33 microseconds.

Figure 4-8 MPU RAM
(Part of 034634-XX B)

4-12 Baseball™

**Figure 4-9 Address Decoding Circuitry
(Part of 034634-XX B)**

(The period of any periodic waveform is the measurement of the time it takes to complete one full cycle.) The 750 KHz clock outputs are generated by the 4H signal. This 4H frequency is generated by the horizontal sync counter R4 to produce the Φ_0 clock input.

Watchdog RESET

(See Figure 4-6)

The reset counter in the MPU control circuitry is a 4-bit decade counter, A4. The Q_D output of this counter is the RESET signal to the MPU. Counter A4 counts the times the

128V signal changes states. On every high-to-low transition of 128V, the counter advances to the next count in its sequence. Meanwhile, the WATCHDOG signal, generated by the MPU at various times during its normal instruction sequence, is resetting the counter back to zero. If for some reason, the MPU program has strayed from its intended instruction sequence and the WATCHDOG signal does not occur before this counter counts up to a point where the Q_D output goes high, a RESET signal is received by the MPU. The RESET signal causes the MPU to restart its instruction sequence from the beginning of the program.

d. alphanumerics generator

(See Figure 4-10)

All score board information at the top and bottom of the TV monitor is generated by the alphanumerics generator. The information is actually generated by alphanumerics PROM N7. This PROM is addressed by latched MPU RAM data signals RAMD0 thru RAMD7.

The scoreboard picture components are each displayed as two side-by-side 8-line-by-4-bit blocks of video on the TV monitor screen. The MPU writes alphanumerics "picture select" data into the MPU RAM during Φ_2 . During Φ_2 , the MPU RAM is accessed by horizontal and vertical sync signals, a process referred to as direct memory access (DMA). The data output from the MPU RAM (RAMD0 thru RAMD5, RAMD7) is-latched and applied to the input of the alphanumerics PROM N7. This address information selects one of the 64 possible alphanumeric characters to be displayed. The actual line of the alphanumeric character to be displayed is defined by vertical sync signals 1V, 2V and 4V and horizontal sync signal 4H. These four signals address the graphics PROM and cause it to either output a normal alphanumeric character or an "upside-down"

alphanumerics character. This is done so that the two players' scoreboards (on opposite sides of the screen) appear in the proper orientation. This inversion is controlled by HREFCNTL, which is generated by RAMD6 latched at the output of latch M7.

The data output of the alphanumeric PROM is applied to data selector/multiplexer N8. If horizontal reflect control signal HREFCNTL is low, the data is loaded into shift register P8 in the same order as output from the alphanumeric PROM. However, if HREFCNTL is high, the data input to shift register P8 is reversed. Therefore, HREFCNTL not only causes the TV monitor character to be inverted vertically, but it is also inverted horizontally.

Shift register P8 is loaded only during the period when HBLANK* and 256H* are both low. (This is the narrow strip at the top and bottom of the screen where the players' scoreboard and other miscellaneous messages are displayed.) This results in a high ALPHASCAN signal that enables a load signal output from NAND gate N9 when both 1H and 2H are high. When 1H goes low P8 shifts four bits of the alphanumeric character out at a 6-MHz rate.

**Figure 4-10 Alphanumerics Generator
(Part of 034634-XX B)**

Figure 4-11 Display RAM
(Part of 034634-XX B)

e. display ram

(See Figure 4-11)

The display RAM stores information from the MPU that defines the horizontal location, vertical location and picture of both the playfield objects (baseball diamond) and motion objects (players, ball and bat). The display RAM consists of four pairs of RAM devices, F2 and F4 (DRAM0), H2 and H4 (DRAM1), J2 and J4 (DRAM2) and K2 and K4 (DRAM3). Each pair contains 256 8-bit bytes of information.

The MPU addresses the display RAM during the Φ 2 period ($4H$ is low) through tri-state buffers L2 on address lines ABUS1 thru ABUS4 and ABUS6 thru ABUS9. The MPU selects the display RAM pair to be written to with address lines ABUS0 and ABUS5, when \overline{DRAMWR} goes low at the input of decoder E3. At this time data is written into the display RAM via data bus lines DBUS0 thru DBUS7.

During the Φ 1 period ($4H$ is low), the display RAM receives its address from either of two different sources. When the TV monitor is actually scanning a horizontal line ($256H$ is low), the display RAM outputs playfield data to the graphics generator. The graphics generator receives its data for playfield pictures when display RAM memory is directly accessed (DMA process) by horizontal and vertical sync signals through tri-state buffers L4. When the monitor is in horizontal blanking ($256H$ is low), the display RAM outputs

motion object data to the graphics generator. The graphics generator receives its data from motion object pictures when the display RAM memory is directly accessed (DMA process) by horizontal sync signals through tri-state buffers M4.

The outputs of the display RAM are selected by data selector multiplexers F3, H3, J3 and K3. These data selector multiplexers are controlled by the data selector multiplexer L3. During horizontal blanking ($256H$ is low) and when $4H$ is low, display data (DISD0 thru DISD7) is output to the graphics generator (for motion objects). During horizontal scan time ($256H$ is high) and when $4H$ is low, horizontal sync $8H$ and vertical sync $8V$ select the data byte which is output to the graphics generator (for playfield objects).

When $4H$ goes high, the MPU selects the display RAM data byte (via address lines ABUS0 and ABUS5) which is output from the MPU. The display RAM is read by the MPU on data lines D0 thru D7. Selected display RAM data is latched into tri-state latch E4 with each rising edge of $1H$. When display RAM read \overline{DRAMRD} goes low, the latched information appears at the D0 thru D7 output of latch E4.

The multiplexed data byte output D1S0 thru D1S7 is latched at the output of latch D4 (PIC0 thru PIC7). This data byte of information contains the following: PIC0 thru PIC5 defines the actual playfield picture to be generated by the graphics generator. PIC6 (when high) reverses the generated picture horizontally. PIC7 (when high) reverses the picture vertically.

f. graphics generator

(See Figure 4-12)

The graphics generator generates the video for the playfield (baseball diamond) during horizontal scan time. During horizontal blanking, the graphics generator generates the motion object signals (players, ball and bat) that are written into the motion object RAM.

For motion objects, display data DISD8 thru DISD15 from the display RAM defines the vertical scan line where there is a motion object to be displayed. When sync signals 8V thru 128V are equal to this number, at the next rising edge of 4H and MATCH signal is latched at the output of latch F6. At this time latch F6 outputs LINE0, LINE1 and LINE2. The binary count of LINE0 thru LINE2 indicates which vertical line of the motion object picture is to be scanned.

The actual graphics pictures are stored in graphics ROMs C5 and D5. Address inputs PIC0 thru PIC5 from the display RAM define the actual picture to be output by the ROMs. The vertical line of the picture is defined by address inputs GA6 thru GA8. These signals originate from vertical sync signals 1V thru 4V for the playfield pictures. For the motion object pictures, these signals originate from the compared output of adder F5.

If PIC7 is low, the output of Exclusive OR gates D6 counts from 0 to 7. If PIC7 is high, the outputs of D6 count from 7 to 0. Therefore, PIC7 reverses the vertical order of the output graphics ROMs C5 and D5.

The data output from the graphics ROMs is applied to two data selector multiplexers B6 and C6. If the output is a motion object, B6 and C6 are enabled by MATCH at the input of OR gate K7. For a playfield object, B6 and C6 are enabled by 256H* (horizontal scan time). The inputs of B6 and C6 are arranged so that if PIC6 is low, the outputs are loaded into shift register A6 with graphics data GD0 shifted out first and GD7 out last. If PIC6 is high, GD7 is shifted out first and GD0 last. Therefore, PIC6 reverses the horizontal order of the graphics data output.

Shift register A6 is loaded every 8H and shifted out at a 6-MHz rate. The output of A6 is inverted by B7 and applied to the motion object RAM data input. It is also gated with the playfield gate (PLFDGATE) signal at the input of AND gate K8. If PLFDGATE is high, it means that the horizontal scan is out of the area reserved for the alphanumerics generator and in the playfield area. Playfield video PLFDVID is applied to the video summing circuitry. Motion object signals are applied to the input of the motion object RAM as RAWVID.

g. motion object ram

(See Figure 4-13)

The motion object RAM stores the video for sixteen 8-bit wide motion objects, then outputs the object video bits in their proper locations during the time of scanning that horizontal line.

During the horizontal blanking period, display RAM data DISD16 thru DISD23 presets binary counters J6 and K5 when HLD goes low. When HLD goes high, the counters increment their count output one count for each rising edge of 6 MHz. The count output is received by RAM K6 as its address input. For each count, one bit of motion data from the graphics generator is written into RAM K6. The counters increment their output seven counts, then HLD again goes low, presetting the counters with a new horizontal location number. This process is repeated seven times.

Shortly after the beginning of the horizontal scan period (256H is high), counters J6 and K5 receive a HCLR pulse that sets the count output to zero. When HCLR goes high, the counters begin counting from 0 to 255, again at a 6-MHz rate. At each address count, motion object data is output from the RAM to the video summing circuit.

Figure 4-12 Graphics Generator
(Part of 034634-XX B)

**Figure 4-13 Motion Object RAM Circuitry
(Part of 034634-XX B)**

h. video summing circuitry

(See Figure 4-14)

The video summing circuitry receives ALPHA from the alphanumericics generator PLFDVID (playfield video), from the graphics generator and MVID (motion object video) from the motion object RAM. These three signals are summed through various gates into flip-flops P9. The actual video to be displayed on the TV monitor is determined by the combination of the two signals at the outputs of flip-flops P9. These outputs (P9, pins 5 and 9) are mixed with HSYNC and VSYNC for a composite VIDEO OUT signal.

Figure 4-14 Video Summing Circuitry
(Part of 034634-XX B)

i. switch and trak ball™ input circuitry

(See Figure 4-15)

Player Trak Ball information, player switch inputs and the game option switches are read by the MPU on data lines D0 thru D7. The three timing signals that control which inputs are read on which data lines, and when, are $\overline{IN0}$ and $\overline{IN2}$ from the address decoding circuitry and \overline{CTRLD} from latch F8 that is shown on Figure 4-17.

When $\overline{IN0}$ and \overline{CTRLD} are both low, horizontal and vertical direction of both Trak Balls are read by the MPU on data lines D0 thru D3 and player 1 switches are read on lines D4 thru D7. When $\overline{IN0}$ is low and \overline{CTRLD} is high, the horizontal rate of player 1's Trak Ball is read by the MPU on data lines D0 thru D3. The vertical rate of player 1's Trak Ball is read on lines D4 thru D7.

When $\overline{IN2}$ and \overline{CTRLD} are low, the game option switches are read by the MPU on data lines D0 thru D3 and the switches for player 2 are read on lines D4 thru D7. When $\overline{IN2}$ is low and \overline{CTRLD} is high, the horizontal rate of player 2's Trak Ball is read on data lines D0 thru D3. The vertical rate of player 2's Trak Ball is read on lines D4 thru D7.

j. display pcb and coin counter outputs

(See Figure 4-16)

For a diagram of the display PCB, see Figure 4-3, Game Wiring Diagram.

The anode of all the game LEDs are strobed at the rate of 64V. The MPU lights an LED by first outputting data on bus lines DBUS0 thru DBUS3. With the proper address from the MPU, OUT3 goes low and latches the data at the output of latch F9. A high on any output causes its transistor to conduct.

The coin counter is tripped when the address decoding circuitry outputs a COIN CNTR signal. The high COIN CNTR signal causes Q2 to conduct.

Figure 4-15 Switch and Trak Ball Inputs
(Part of 034634-XX B)

Figure 4-15 (Continued) Switch and Trak Ball Inputs

Figure 4-16 Display PCB and Coin Counter Outputs
(Part of 034634-XX B)

k. audio circuitry

(See Figure 4-17)

The audio circuitry produces crowd noise, HIT and WHISTLE audio. The crowd sound is the result of the gated random noise generator composed of shift registers A8 and B8. The crowd sound volume is selected by the MPU through data bits DBUS0 thru DBUS3. The noise (unfiltered crowd sound) is filtered by the active bandpass filter circuit comprised of one quarter of op-amp A9 (LM324).

The HIT audio is generated from latched data signal DBUS1 from the MPU.

The WHISTLE sound is generated by timer C9 when DBUS0 is latched high.

The three sounds are summed at the input of op-amp A9 (one quarter of LM324) and fed to the volume control. The signal is then fed to the TDA2002 amplification circuit.

The ATTRACT signal is generated from the MPU via DBUS5 input to latch E8. When ATTRACT is high, the audio signal is grounded by conducting transistor Q11.

illustrated parts catalog

The purpose of this chapter is to provide you with information for ordering replacement parts for your Baseball™ game.

When ordering parts from your distributor, give the part number, part name, applicable figure number of this catalog, and serial number of your game. This will help to avoid confusion and mistakes in your order. We hope the results will be less downtime and more profit from your game.

**Figure 5-9 Harness/Switch Assembly
A034564-01**

| Item | Part No. | Qty. | Description |
|------|------------|------|--|
| 1 | A034563-01 | 1 | Main Harness |
| 2 | A034631-01 | 1 | On/Off Switch Assembly |
| 3 | 68-002 | 2 | DPDT Interlock Switch, Cherry #E79-30A |
| 4 | 000268-02 | 2 | Interlock Switch Mounting Bracket |
| 5 | A030169-01 | 1 | Audio Control/Test Switch Assembly (Rev. G), consisting of the following four items: |
| 5a | 030168-01 | 1 | Mounting Bracket |
| 5b | 69-001 | 1 | DPDT Slide Switch, Switchcraft #46206LR |
| 5c | 72-6008S | 2 | #10 x 1/2" Cross-Recessed Pan-Head Type AB Zinc-Plated Steel Thread-Forming Screw |
| 5d | 19-9032 | 1 | Wirewound Panel-Mounting Variable Resistor, Ohmite Model E, #0110 Rheostat |
| 7 | 79-3210 | 1 | Single-Pole .25" Quick-Disconnect Tab Fuse Block |
